

ABSTRACT OF THE DISCLOSURE**LEGACY CORBA NAME SPACE INTEGRATION USING WEB APPLICATION
5 SERVERS**

10 A method, apparatus, and computer implemented instructions for binding object references from a remote name space into a local name space using a Web application. Information is collected to generate a request for an object reference. Information, such as an application server to use as the source, a source name space path, an identification of destination server, and a destination name space path to which the object
15 reference is to be bound, may be used. The request is sent using a communications protocol, such as hypertext transfer protocol to the application server to be used as the source for the object reference. An object reference is located using the name space The object reference
20 may be serialized into a format, such as a common object request broker architecture format and sent to the destination. The destination will unserialize the object reference and perform binding using the destination name space path.
